**The National Archives of  
Australia: Approach to  
digital preservation**

**Andrew Wilson & Cornel Platzer  
National Archives of Australia:  
Digital Preservation Project  
15 September 2004**

# Topics

- concepts (Andrew)
- implementation (Cornel)
- XENA demo (Andrew)

# Concepts

NATIONAL ARCHIVES OF AUSTRALIA

# Essential performance model

- idea of ‘essential performance’ is central to the NAA approach
- two significant components to this:
  - **performance**
  - **essence**

# Traditionally

- records are experienced directly as objects

- preserving the object is how we preserve the 'record'

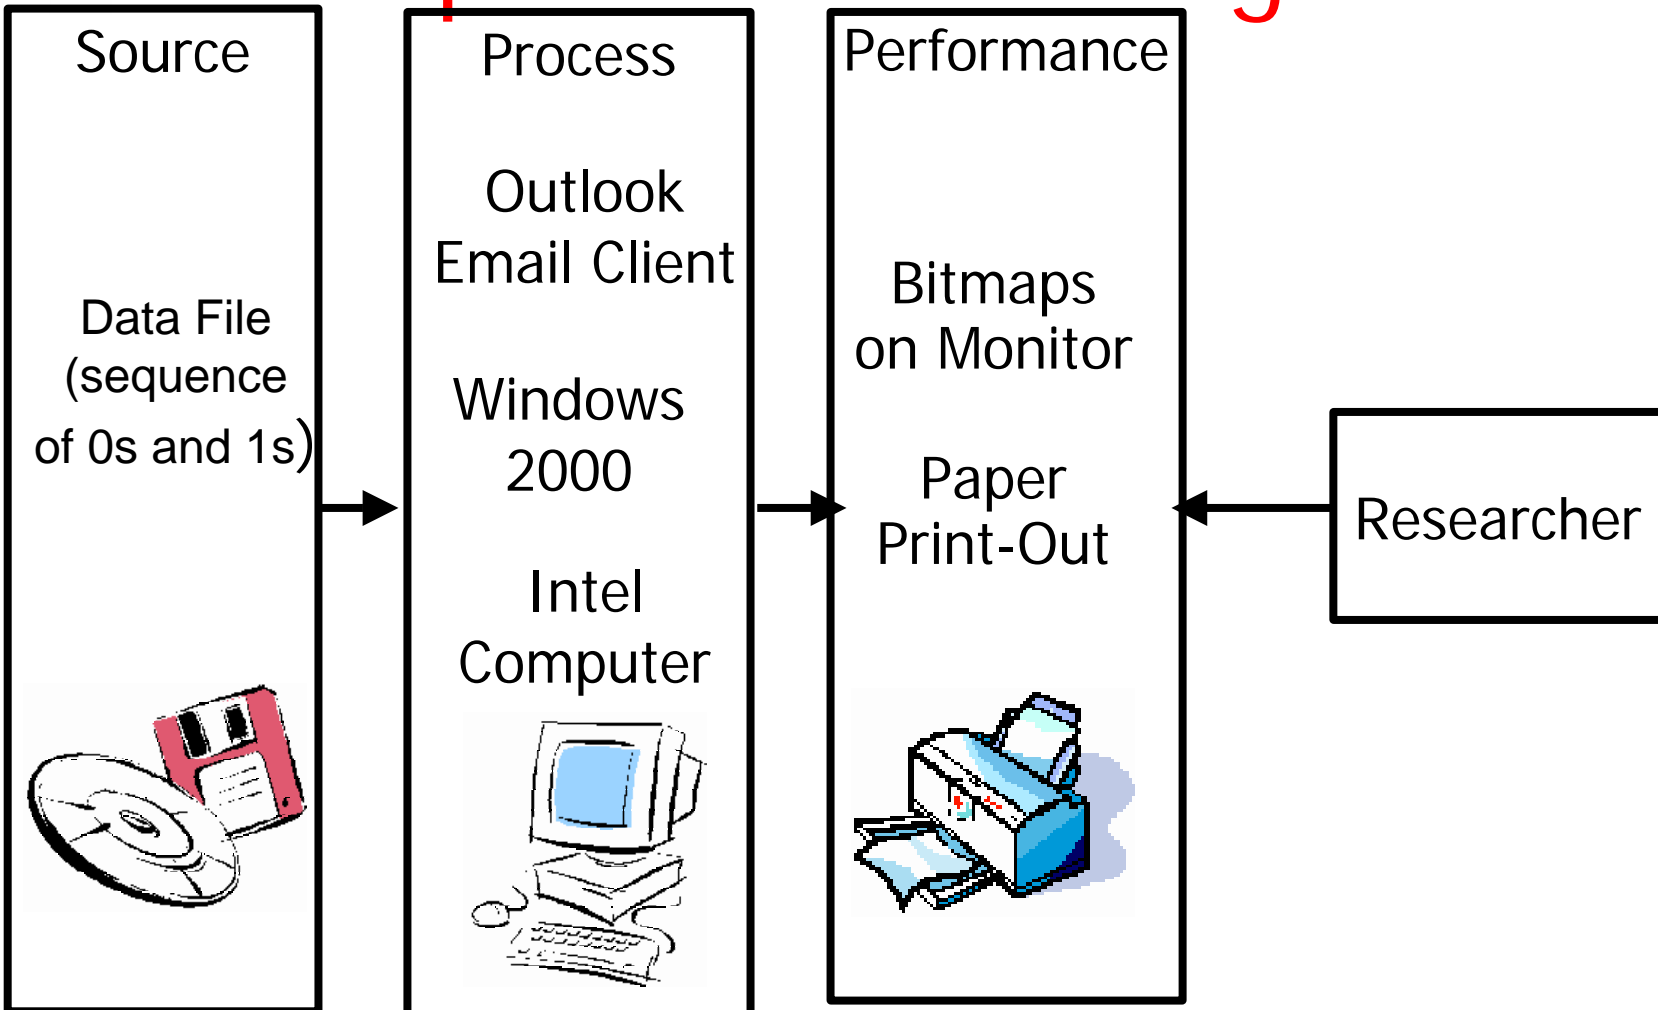

# Electronic records are different

- 'record' is experienced as a performance

- preserve the performance and we preserve the 'record'

# Example: email message

# Keeping source + process doesn't work

- media is fragile and fails
  - need to refresh the source
- components become obsolete
  - technological and marketplace obsolescence
- components are proprietary and licensed (not purchased)
  - software licenses don't last forever!

so...we need a different  
approach

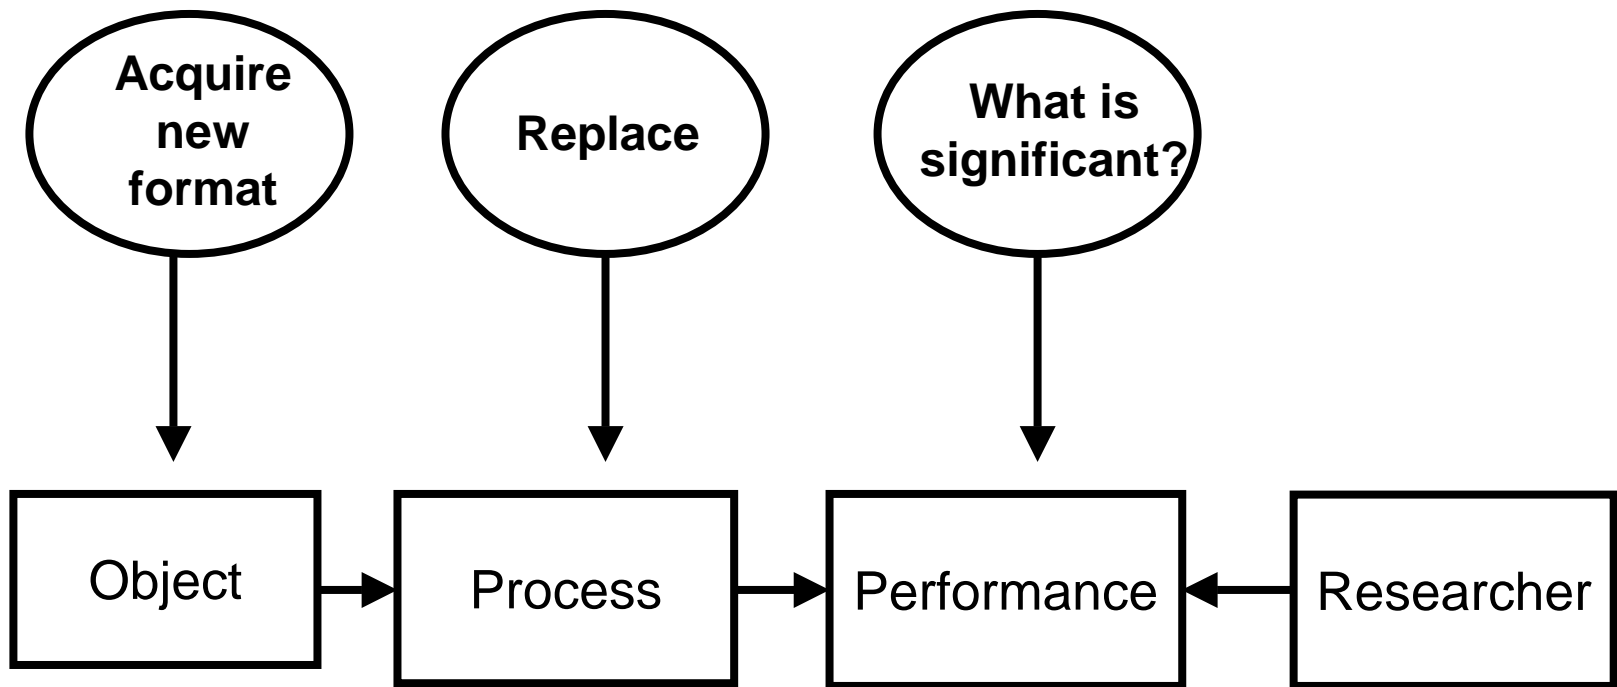

but what?

# Components of the approach

1. what is significant about the performance  
– what is the *essence*?
2. what format best expresses the *essence*?
3. what do we use to manage the new source  
(*essence*) in a way that allows us to  
reproduce the performance at will?

# Preserving performances

# 1. What is significant?

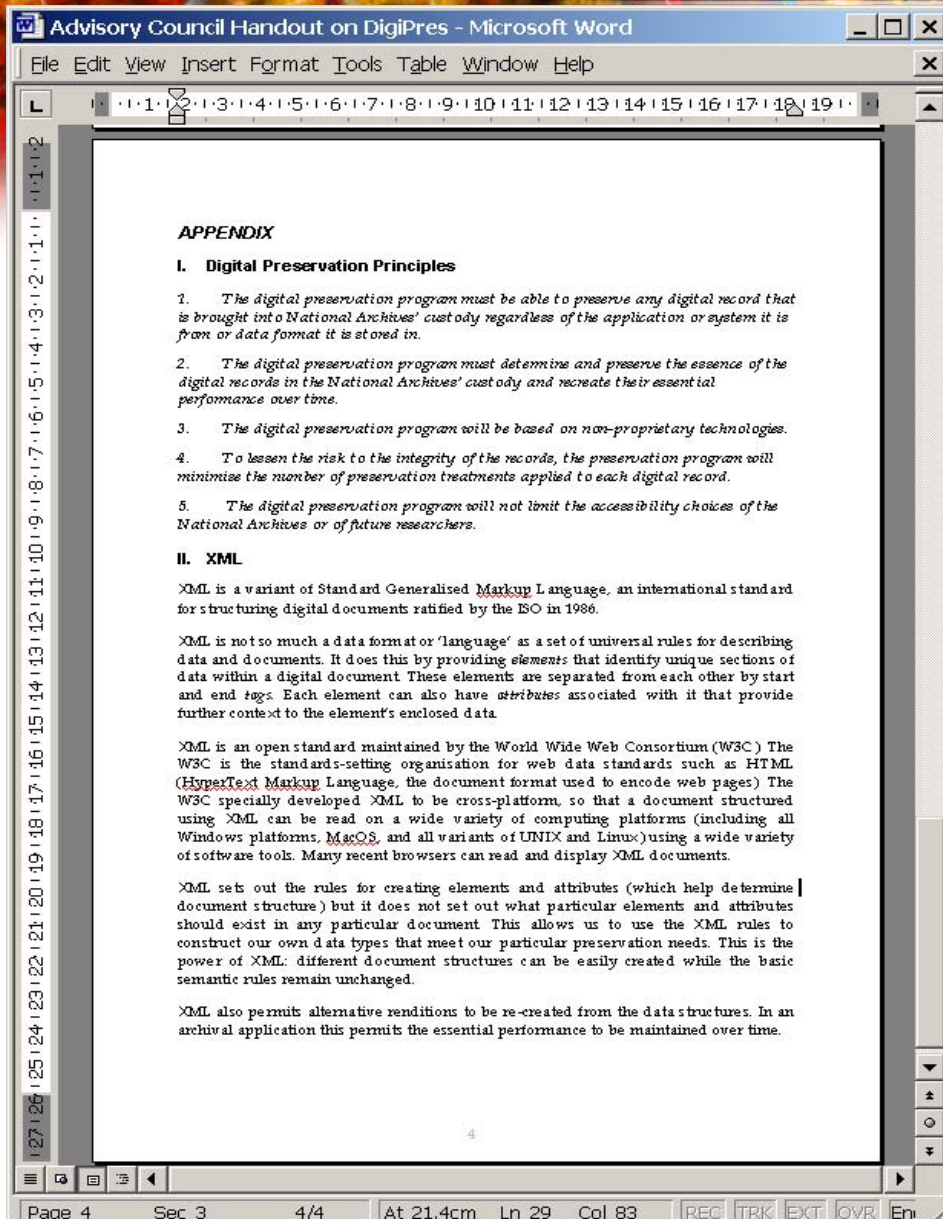

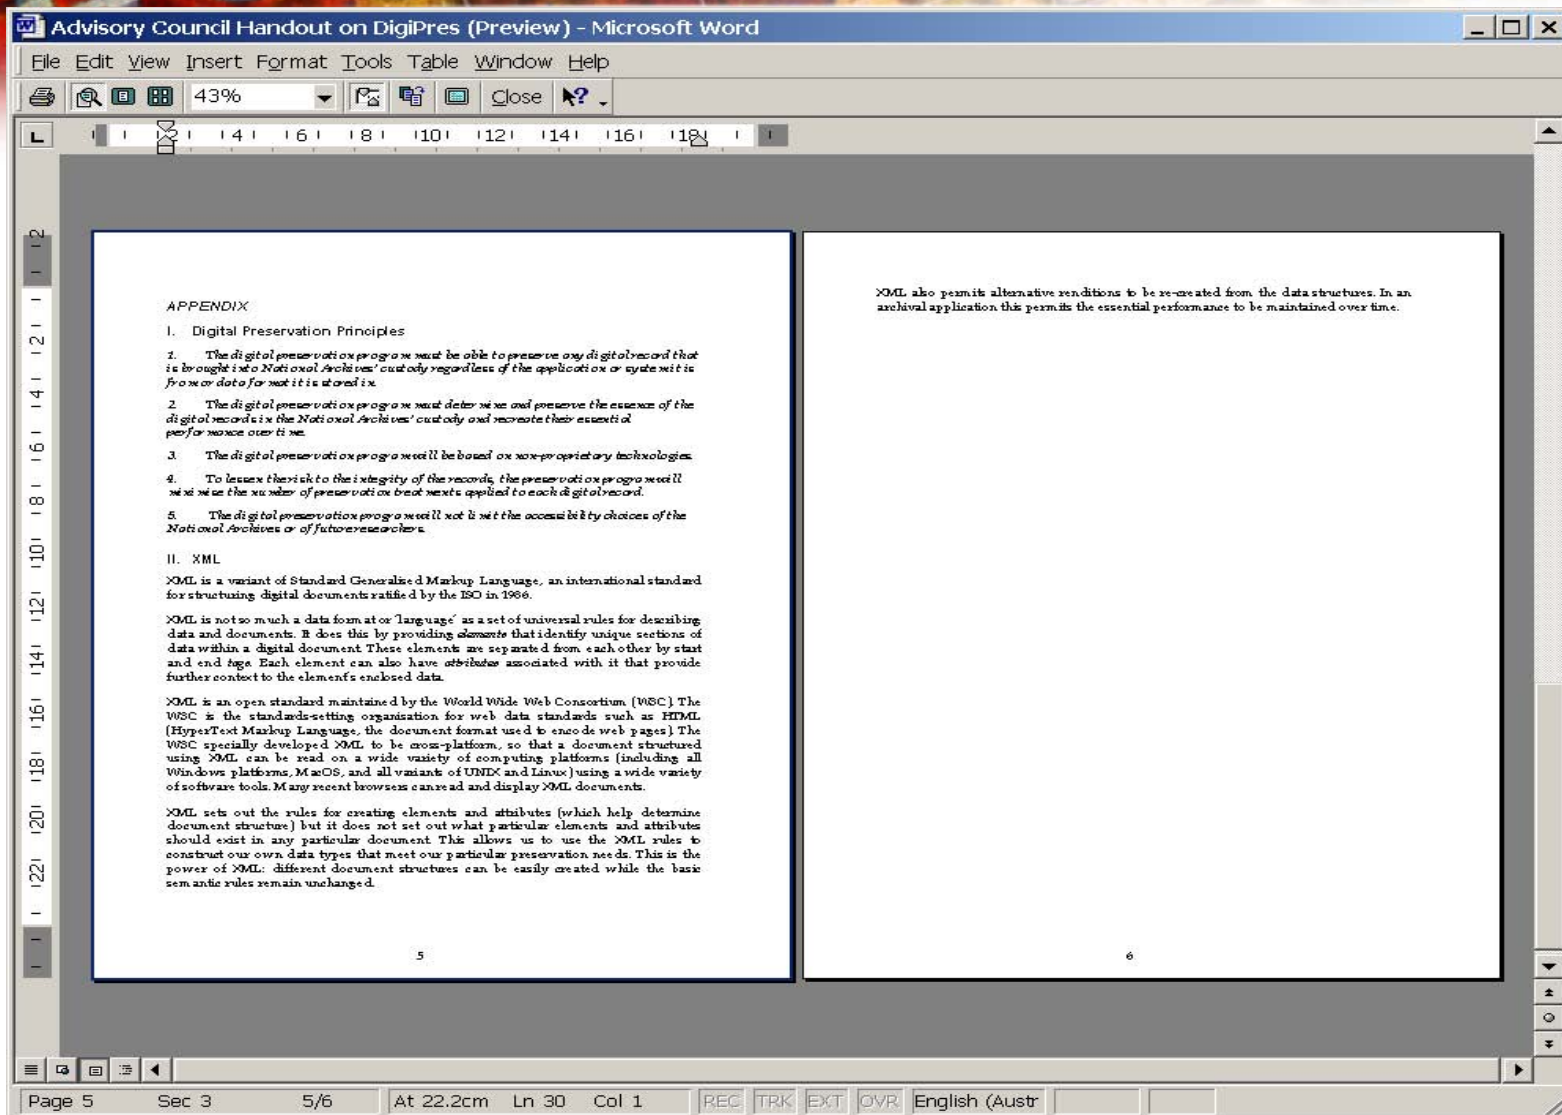

Determine the essential aspects of the performance  
*The essence of the record*

# The 'essence' of the record

- what we want to preserve out of the performance
  - what aspects are essential to the record's value?
  - what aspects are incidental to the record's value?
- consider census records
  - microfilm copies capture the essence of the census return so no need to keep originals

## 2. What format?

Normalise into open, fully documented data formats that can represent that essence

*Formats based on XML*

# Normalisation

- don't try to preserve the original process at all
- develop our own processes using open public-domain standards
- commit to maintain those processes over time
- one-off conversion of the source to suit *our* processes
- we set our own preservation platform
  - Not reacting to others
- aids authenticity by not changing the master regularly

### 3. What tool?

Acquire technologies to manage those formats

*Our tool: Xena*

# Xena

- our tool for preserving the ‘essential performances’
- it normalises data objects and...
- ...it re-presents performances
- written in Java
  - Windows, Linux, Mac OS X
- open under the GPL
- latest at: [sourceforge.net/projects/xena/](http://sourceforge.net/projects/xena/)

# III XENA

(xml electronic normalising of archives)

NATIONAL ARCHIVES OF AUSTRALIA

# XENA core

The core consists of:

- I. graphical user interface components
- II. plug-in management components
- III. generic validation components

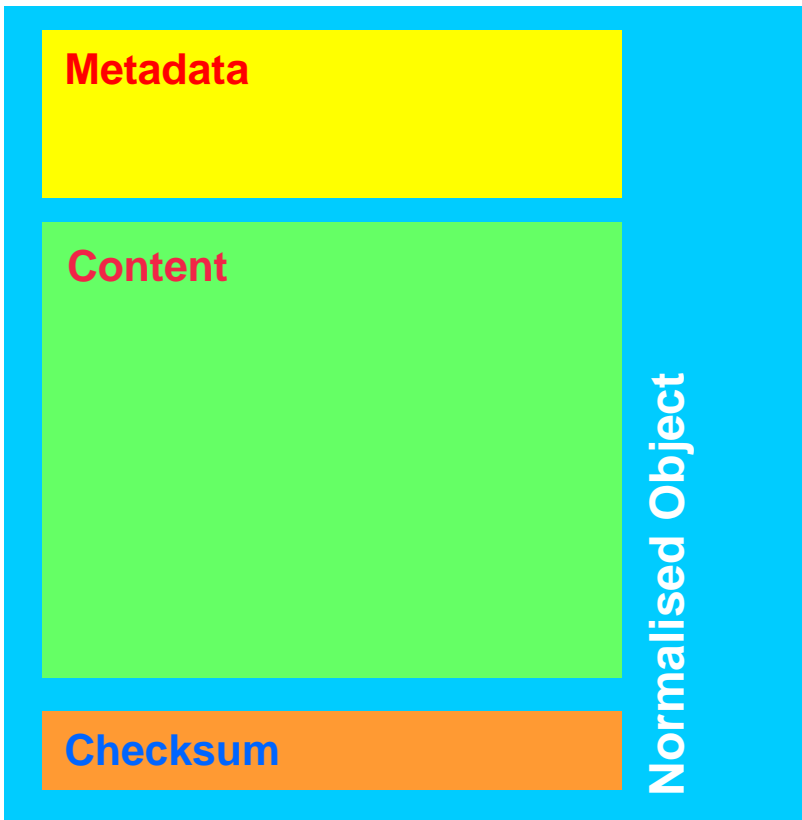

# XENA plug-ins

Plug-ins are created for identified data types that are to be processed. Each plug-in includes:

- guesser component
- one or more input format type components
- normalised format type (xml schema)
- one or more normalisation modules
- one or more view components
- validation functionality

# A 'xena'd' object

**What the Xena  
normalisation  
process produces: a  
wrapped object**

And now the demonstration ...
